ABSTRACT

Introduction: Cardiovascular disease (CVD) is a major cause of death and disability worldwide. The most stringent primary CVD screening guidelines in developed countries use absolute CVD risk scores or coronary heart disease, such as Framingham or SCORE (Systematic Coronary Risk Evaluation) there are two types of CVD risk factors: namely modifiable risk factors and non-modifiable risk factors. The aim of the current study is to determine the profile of potentially modifiable and non-modifiable cardiovascular risk factors. Method: This research consists of 41 elderly people aged ≥60 years in Guguak Kabupaten 50 Kota, West Sumatera, Indonesia. The data taken is modifiable risk factors consisting of diseases related risk factors including blood pressure categories, lipid profile, central obesity, body mass index, lifestyle-related risk factors such as smoking habit. We also take data of non-modifiable risk factors such as age and gender. The results: This study consists of 41 elderly people aged ≥60 years in Guguak Kabupaten 50 Kota, West Sumatera, Indonesia. The mean age of elderly was 68 ± 7.64861 years old consisting of 29.3% men and 70.7% women, 34% of elderly with hypertension, the elderly with hypercholesterolemia 71%, hypertriglyceridemia 41%, and the elderly women with low HDL-C levels were 53%, the elderly men with low HDL-C levels were 92%. Conclusion: There are two types of risk factors CVD, modifiable risk factors and non-modifiable risk factors. The modifiable risk factors consisting of diseases related risk factors including blood pressure categories, lipid profile, central obesity, body mass index, and lifestyle-related risk factors such as smoking habit.

INTRODUCTION
Cardiovascular disease (CVD) is a major cause of death and disability worldwide. Estimate d, two thirds (63%) of premature death at age 15 ± 69 years, with the main cause of CVD. It has been predicted that by 2030, more than 23.3 million people will die each year due to CVD(1). Early detection and treatment of at-risk individuals is an important strategy in preventing or delaying the occurrence of CVD, thereby reducing the health and economic burden. The most stringently primary CVD screening guidelines in developed countries use absolute CVD risk scores or coronary heart disease, such as Framingham or SCORE (Systemic Coronary Risk Evaluation)(2)(3) there are two types of CVD risk factors namely modifiable risk factors and unmodifiable risk factors(2)(4). The aim of the current study is to determine the profile of potentially modifiable and unmodifiable cardiovascular risk factors.

METHODS
This research consists of 41 elderly people which age ≥ 60 years in Guguk, Kabupaten 50 K t a, West Sumatera, Indonesia. The data taken is modifiable risk factors consisting of diseases related risk factors including blood pressure categories, lipid profile, central obesity, body mass index and lifestyle related risk factors such as smoking habit. We also take data of unmodifiable risk factors such as age and gender.

Risk factors of CVD including age, gender, blood pressure categories which consists of normal range, prehypertension, and hypertension, lipid profile to get a description of dyslipidemia consisting of hypercholesterolemia, hypertriglyceridemia and decreased LDL levels, central obesity with waist circumference ≥ 95 cm, body mass index consists of normal BMI, overweight and obese and smoking habit.

RESULT AND DISCUSSION
This research consists of 41 elderly people which age ≥ 60 years in Guguk, Kabupaten 50 K t a, West Sumatera, Indonesia. The results of this study, the mean age of elderly were 68±7.64861 years old that consisting of 29.3% men and 70.7% women.

a. Blood Pressure Categories
The blood pressure categories in this study were normotension if systolic blood pressure <120 mmHg and diastolic blood pressure <80 mmHg, hypertension when systolic blood pressure ≥140 mmHg, and diastolic blood pressure ≥90 and if prehypertension were excluded from both criteria. In this study, elderly with normotension were 22%, prehypertension were 41% and 34% of elderly with hypertension.

b. Dyslipidemia
Dyslipidemia based on the NCEP (National cholesterol Education program) consists of hypercholesterolemia mean which is total cholesterol (TC)>200 mg/dL, hypertriglyceridemia mean if triglyceride (TG) levels >150 mg/dL and low HDL-C (high density lipoprotein in cholesterol) which levels of HDL-C <65 mg/dL for men and <55 mg/dL for women.

In this study it was found that elderly with hypercholesterolemia 71% and with normal cholesterol levels 29%. The elderly with hypertriglyceridemia mean 41%, and the elderly with normal triglyceride levels 59%. The elderly women with low HDL-C levels were 53%, and elderly men with low HDL-C levels were 92% (Table 1).

C. Central obesity

Central obesity in this study was found to have a waist circumference ≥95 cm. The results of this study found 48.9% of elderly with central obesity. The mean waist circumference in elderly 93.6 ± 9.984 cm with 77 cm minimum value and maximum value of 110 cm (Table 2).

<td>77</td>
<td>110</td>
</tr>
</tbody>
</table>

d. Body Mass Index

Normal BMI if BMI <25 kg/m², overweight if BMI 25 ≤ BMI <30 kg/m² and obese if BMI ≥30 kg/m². In this study, found the elderly with normal BMI were 49.6%, the elderly with overweight were 36.6% and the elderly with obese were 14.4% (Table 3).

e. Smoking Habit

In the study found elderly with smoking habits 27% and elderly did not smoke 73% (Figure 1).

Figure 1. Smoking Habits in Elderly

CONCLUSION

There are two types of risk factors CVD, modifiable risk factors and nonmodifiable risk factors. The modifiable risk factors consisting of diseases related risk factors including blood pressure categories, lipid profile, central obesity, body mass index and lifestyle-related risk factors such as smoking habit.
